

EL6: Data formats

data.table, SQL, DuckDB, parquett, SAS, JSON, API

Reading

- [1, ch. 2] on Databases: it is important to understand some basic concepts. You might, however, ignore sections about “(Hyper)graph databases”. Try to understand the SQL code even though you might not need to write such code on your own.
- H. Wickham, M. Çetinkaya-Rundel, and G. Grolemund [2] [chap 21](#) describes how to connect to a database from R.
- S. R. Fenk, K. Furu, and I. J. Bakken [3] describe why the current common practice with register data delivery in SAS format should be replaced by parquet files. Until this has happened, we often need to use SAS for data extraction.
- [4] introduces the `data.table` syntax, its general form, how to *subset* rows, *select and compute* on columns, and perform aggregations *by group*.

Recommended references:

- V. Arel-Bundock [5] provides a good comparison between base R, dplyr and `data.table`.

Optional practice

We won't focus on SQL in this course but it might still be good to know some of the basics. Two useful resources for your own practicing (if you like): - [SQLzoo](#) - [The SQL Tutorial for Data Analysis](#)

Imaginaed scenario

- You have requested register data from Statistics Sweden (SCB) and The National Board of Health and Welfare (NBHW; SoS)
- After a couple of months (it previously took a year), you receive some huge files with file ending `.sas7bdat`
- What do you do now?

`.sas7bdat`

- Many governmental agencies are using SAS
- Their standard format when delivering big data sets
- SAS is great for handling big data sets (no need to read everything into memory)
- But you don't know how to use SAS 😞

First try

- It is often possible to read medium-sized SAS files to R by `haven::read_sas()`

- Based on the [ReadStat C library](#)
- Based on [reverse-engineering of binary files!](#)
- You need to put some trust that those wizards where good “hackers” (your analyzis and future patients lifes may depend on it) :-)
- But similar trust always applies when you use open source software, which depend on other peoples software, which depends on ...
- But, yes, it is legal according to EU legislation :-)

[Directive 2009/24/EC art 6](#) The authorisation of the rightholder shall not be required where reproduction of the code and translation of its form within the meaning of points (a) and (b) of Article 4(1) are indispensable to obtain the information necessary to achieve the interoperability of an independently created computer program with other programs [...]

But let's say this did not work for your data! 😞

Large SAS files

- Best practice for current SAS version (9.4) is to export only nessecary data to csv
 - SAS Viya (another solution not likely replacing SAS 9.4) can export parquet files
- You need a SAS license (expensive) as well as some SAS syntax for this
 - But you might ask GenAI to generate such code for you
- The exported csv file can later be read into R

i SAS in the course?

We are not using SAS in the course (and it is [no longer available for students to download](#) ... it's to expensive even for a large university ...). Hence, this is just as a future advice if you will work in an organisation with a SAS license (it is still available for employers within GU for a monthly cost).

If statistics programs/languages were cars...

Databases

- a database is a collection of “tables” (tabular data frames)
 - Differences between data frames and database tables:
 - Database tables are stored on disk and can be arbitrarily large.
 - Data frames are stored in memory
 - Database tables almost always have indexes; makes it possible to quickly find rows of interest
 - Data frames and tibbles don’t have indexes, but `data.table`s do, which is one of the reasons that they’re so fast.
 - No fixed row order in a table
-

Those are sometimes used in our field but if so, you will hopefully get some initial help from the IT department who will provide access details etc. Such access is then integrated into R and [Positron](#) (as well as [RStudio](#)). If thi is relevant, you can most likely use tools such as [dbplyr](#) to query the data without to much use of SQL itself.

Cloud

Commercial cloud products are less likely to be used for sensitive health data within our field.

In-process

They're great for working with large datasets locally where you (the statistician) is the primary user. SQLite was a good tool in the past (it might still be but ...) nowadays DuckDB is the most prominent implementation!

SQL

- Different database systems may use different query languages.
- The **Structured Query Language (SQL)** is the most widely used for relational databases.
- Defined by international standards (ANSI/ISO).

What is SQL used for?

SQL is used to:

- Retrieve data (SELECT)
- Filter data (WHERE)
- Aggregate data (GROUP BY)
- Combine tables (JOIN)
- Modify data (INSERT, UPDATE, DELETE)

SQL Dialects

- SQL is a standard, but implementations differ slightly.
- These variations are called **dialects**.
 - **T-SQL** (Microsoft SQL Server)
 - **PL/SQL** (Oracle)
 - PostgreSQL SQL dialect
 - MySQL SQL dialect

Most core functionality is similar across systems.

A Simple Example

```
SELECT name, age
FROM students
WHERE age >= 18
ORDER BY age;
```

This query:

- Selects two columns

- Filters rows
- Sorts the result

Relevance?

- I don't think SQL is a necessary skill to master for most statisticians
- You should nevertheless be aware of its existence and understand simple code examples as above
- If an employer requires SQL skills, you can probably teach yourself enough if/when needed
- Nevertheless, the more languages/tools etc you know, the more competitive you become (but don't sacrifice statistical knowledge for technical. As a statistician, I think it is more important to study statistical theory and methods compared to specific tools).

DuckDB is a fast portable database system

Query and transform your data anywhere using DuckDB's feature-rich SQL dialect

Installation ↓ Documentation

```

1 -- Get the top-3 busiest train stations
2 SELECT
3   station_name,
4   count(*) AS num_services
5 FROM train_services
6 GROUP BY ALL
7 ORDER BY num_services DESC
8 LIMIT 3;

```

Aggregation query ✓ Live demo →

---	---	---	------------------------------------	--

*see our blog post for more details

DuckDB

- Free and open source (backed by foundation)
- Column based
- Very easy to set up
- Very efficient!
- SQL is an option as API language but not a requirement
- Integration by DBMS and “hidden” SQL under the hood: [dbplyr](#)
- A more “native” implementation by [duckplyr](#)
 - Better (but perhaps not as widely used yet and therefore a bit less mature/stable)
- Can be used both with disk data and data in RAM

Example

```
# pak::pak("tidyverse/duckplyr")  
library(duckplyr)
```

Loading required package: dplyr

Attaching package: 'dplyr'

The following objects are masked from 'package:stats':

filter, lag

The following objects are masked from 'package:base':

intersect, setdiff, setequal, union

The duckplyr package is configured to fall back to dplyr when it encounters an incompatibility. Fallback events can be collected and uploaded for analysis to guide future development. By default, data will be collected but no data will be uploaded.

i Automatic fallback uploading is not controlled and therefore disabled, see ``?duckplyr::fallback()``.

✓ Number of reports ready for upload: 57.

→ Review with ``duckplyr::fallback_review()``, upload with ``duckplyr::fallback_upload()``.

i Configure automatic uploading with ``duckplyr::fallback_config()``.

✓ Overwriting dplyr methods with duckplyr methods.

i Turn off with ``duckplyr::methods_restore()``.

```
conflicted::conflicts_prefer(dplyr::filter)
```

[conflicted] Will prefer dplyr::filter over any other package.

```
# Extra tools to connect to internet data
```

```
db_exec("INSTALL httpfs")
```

```
db_exec("LOAD httpfs")
```

```
# Use some online data which is too big to keep in memory
```

```

year <- 2022:2024
base_url <- "https://blobs.duckdb.org/flight-data-partitioned/"
files <- paste0("Year=", year, "/data_0.parquet")
urls <- paste0(base_url, files)

# Connect to the data (without downloading)
flights <- read_parquet_duckdb(urls)
# nrow(flights) # It's not in memory!
count(flights, Year) # processing outside memory

```

```

# A duckplyr data frame: 2 variables
  Year      n
<dbl> <int>
1  2022 6729125
2  2023 6847899
3  2024 3461319

```

Complex queries can be executed on the remote data. Note how only the relevant columns are fetched and the 2024 data isn't even touched, as it's not needed for the result.

```

out <-
  flights |>
  mutate(InFlightDelay = ArrDelay - DepDelay) |>
  summarize(
    .by = c(Year, Month),
    MeanInFlightDelay = mean(InFlightDelay, na.rm = TRUE),
    MedianInFlightDelay = median(InFlightDelay, na.rm = TRUE),
  ) |>
  filter(Year < 2024)

out |>
  explain()

```

```

HASH_GROUP_BY
-----
Groups:
  #0
  #1

Aggregates:
  mean(#2)
  median(#3)

```

DuckDB and Data Files

DuckDB can query files directly:

- Parquet
- CSV

- Arrow
- JSON

No data import (to your computers Random Access Memory [RAM]) is required!

Example

- Let's say you used SAS to export your data to a csv file
- DuckDB can query the relevant data from that file directly and collect only the data you actually need!

```
csv_file <- tempfile(fileext = ".csv")
write.csv(NHANES::NHANES, csv_file)

read_csv_duckdb(csv_file) |>
  filter(Age >= 18) |>
  summarise(BMI_mean = mean(as.numeric(BMI), na.rm = TRUE), .by = Gender)
```

```
Warning: There were 2 warnings in `summarise()`.
The first warning was:
i In argument: `BMI_mean = mean(as.numeric(BMI), na.rm = TRUE)`.
i In group 1: `Gender = "male"`.
Caused by warning in `mean()`:
! NAs introduced by coercion
i Run `dplyr::last_dplyr_warnings()` to see the 1 remaining warning.
```

```
# A duckplyr data frame: 2 variables
  Gender BMI_mean
  <chr>    <dbl>
1 male      28.7
2 female    28.7
```

Parquet

- From Apache Arrow
 - Open format
 - flat files with possible hierarchical structure by transparent structure of folders and filenames
 - very fast to read
-

Example

- So we might work with CSV + DuckDB but it is even more efficient if we could convert the CSV to a parquet file
- The solution below reads the CSV data and then export it to a new parquet file
- This means that all data must still fit into memory
 - If it doesn't, do it chunk-wise (piece by piece, 1 M rows at the time or similar)

```
# install.packages("arrow")
library(arrow)
parquet_file <- tempfile(fileext = ".parquet")
read_csv_arrow(csv_file) |>
  write_parquet(parquet_file)
```

```
# Now
read_parquet_duckdb(parquet_file)
```

```
# A duckplyr data frame: 77 variables
      C0      ID SurveyYr Gender   Age AgeDecade AgeMonths Race1 Race3
Education
      <int> <int> <chr>    <chr>  <int> <chr>         <int> <chr> <chr>
<chr>
1      1  1 51624 2009_10  male    34 " 30-39"         409 White <NA>  High
```

```

```

tidy data

- duckplyr let's you use the familiar dplyr/tidyverse syntax
- If certain steps in your pipeline are not compatible with DuckDB, data might be collected into memory and the pipeline continues nevertheless
- After filtering/aggregation etc you can always choose to collect() the data and use your ordinary workflow from there

Data files

.qs2

A fast, compressed R-specific binary format used for caching by the {targets} package.

Data must be fully read from disk into memory (RAM), typically via `targets::tar_read()`.

.sas7bdat

A proprietary binary format used by SAS and commonly encountered in register data deliveries.

It can be imported into R (e.g. with `haven::read_sas()`), and some tools allow selection of specific columns at import.

The dataset is generally read into memory.

.csv (Comma-Separated Values)

A plain-text format following a loosely defined standard.

It is human-readable but inefficient for large datasets.

Tools such as DuckDB (via {duckplyr}) can read only the required columns and rows and perform filtering and aggregation during import.

.parquet (Apache Parquet)

A columnar, compressed, and standardized binary format designed for efficient analytics.

It supports selective column access and integrates well with modern analytical engines such as DuckDB and Arrow.

Faster in memory?

- DuckDB and {duckplyr} makes it possible to work with data which does not fit into memory
- But what if data would fit (which is more common)?
 - You can use tibbles and dplyr etc as usual ...
 - ... but it might be sloooooooooooooow ... for big enough data
 - (Although dplyr also gets some [speed improvements](#) from time to time)
- {data.table} is much more efficient!

data.table

- An R package (not a data storage format or a database system)
- Comparable to working with data.frame in base R or tibble in the tidyverse
- Sometimes described as a Domain Specific Language (DSL) within R
- Introduced in 2006 (mature, stable, and widely used — older than the tidyverse)
- Provides faster alternatives to several base R functions: fifelse(), fcase(), forder(), fread(), fcoalesce(), as.IDate(), %chin%
- Core components implemented in C for performance
- Uses concepts similar to databases:
 - Integer-based keys and indices
 - Efficient joins and grouping
- Reference semantics (modifications by reference — avoids unnecessary copying)
- Very flexible and compact syntax (powerful, but sometimes perceived as unusual at first)
- Strongly appreciated by many statisticians — unknown to some — and slightly intimidating to others 😊

Copy-on-modify

- Assume df is a large data.frame/tibble with many rows and columns, one of them called old. Let f() be some function.
- What happens when you add a new column using
df\$new <- f(df\$old) or df <- mutate(df, new = f(old))?

- Even though you reuse the name `df`, R typically creates a modified copy of the object.
- In R, objects use *copy-on-modify* semantics:
 - When an object is changed, a new copy is created (if needed).
 - The name `df` is just a reference to an object in memory.
 - After reassignment, `df` refers to the new object.
- The previous object may remain in memory temporarily until garbage collection runs.
- For very large objects, this can result in substantial temporary memory use

Reference semantics

- In `data.table`, reference semantics are used instead.
- You can modify the existing object directly: `df[, new := f(old)]`
- Or delete columns in place: `df[, old := NULL]`
- No full copy is made — the object is modified by reference.
- There is still only one object in memory (and it is still called `df`).

Example

```
library(data.table)
dt <- NHANES::NHANES
setDT(dt)
setkey(dt, ID) # Use the ID column as index
# How many adults by gender do we have
dt[Age >= 18, .N, Gender]
```

```
Gender      N
<fctr> <int>
1:  male  3686
2: female 3795
```

```
# Mean BMI by gender
dt[Age >= 18, mean(BMI, na.rm = TRUE), Gender]
```

```
Gender      V1
<fctr>    <num>
1:  male 28.67528
2: female 28.66978
```

```
# Convert all factors to characters
dt[, names(.SD) := lapply(.SD, as.character), .SDcols = is.factor]
```

joins

```
x[i, on, nomatch]
| | | |
| | | \_ If NULL only returns rows linked in x and i tables
| | \___ a character vector or list defining match logic
| \___ primary data.table, list or data.frame
\___ secondary data.table
```

Join type	data.table	SQL	dplyr
Right join	DT1[DT2]	RIGHT JOIN	right_join(DT2, DT1)
Left join	DT2[DT1]	LEFT JOIN	left_join(DT1, DT2)
Inner join	DT1[DT2, nomatch = 0]	INNER JOIN	inner_join(DT1, DT2)
Full join	merge(DT1, DT2, all = TRUE)	FULL OUTER JOIN	full_join(DT1, DT2)
Anti join	DT1[!DT2]	NOT EXISTS	anti_join(DT1, DT2)
Semi join	DT1[DT2, nomatch = 0][, unique(.SD)]	EXISTS	semi_join(DT1, DT2)
Rolling join	DT1[DT2, on = "date", roll = TRUE]	—	join_by() + rolling
Non-equi join	DT1[DT2, on = .(x >= lower, x <= upper)]	—	join_by(x >= lower, x <= upper)
Update join	DT1[DT2, value := i.value]	UPDATE ... JOIN	DT1 %>% left_join(DT2) %>% mutate(...)

External API

- We previously assumed you get some data delivery from a register holder
- Or maybe you work within the organization where data is collected, and therefore have access to the original data base.
- Some data can also be openly accessed by an Programming Application Interface (API)
- The PX-WEB API is used by a large number of statistical authorities (and others) world-wide to provide access to aggregated data
- The {pxweb} R package simplifies the process

Available resources

name	value
api.scb.se	Statistics Sweden
statfin.stat.fi	Statistics Finland

name	value
pxwebapi2.stat.fi	Statistics Finland (old version)
statistik.sjv.se	The Swedish Agricultural Agency
fohm-app.folkhalsomyndigheten.se	The Public Health Agency of Sweden
statistik.konj.se	The Swedish National Institute of Economic Research
prognos.konj.se	The Swedish national institute of economic research, forecast database
statdb.luke.fi	LUKE Natural Resources Institute Finland
vero2.stat.fi	Verohallinto - Finnish Tax Administration
px.hagstofa.is	Statistics Iceland
statistik.linkoping.se	Linköping municipality in Sweden

pxweb.nordicstatistics.org	Nordic Statistics Database
pxweb.stat.si	SiStat Database

Example

- Let's say we work with cancer data from whole Sweden
 - We have access to the number of diagnosed individuals for each month, region,
 - Let's explore some health data for Sweden.
 - The first time you need the data, use `pxweb_interactive()` from your console.
 - It will guide you through all the necessary steps.
 - It will then provide you the necessary R code to replicate the query
-

```
library(pxweb)
```

```

  theme(legend.position = "bottom") +
  scale_y_continuous(
    labels = scales::label_number(scale = 1e-6, suffix = "M")
  )

```

Hierachical data

- We like tabular data!
- If we get wide data we can transform it to long data (and vice versa)
- But we might sometimes encounter more hierarchical data structures
- JSON (JavaScript Object Notation) most popular
- XML is aother format (used by the IRS/Skatteverket etc when they export population data)

```
{
  "system": "ICD-10",
  "chapter": {
    "code": "Chapter I",
    "title": "Certain infectious and parasitic diseases",
    "range": "A00-B99",
    "blocks": [
      {
        "code": "A00-A09",
        "title": "Intestinal infectious diseases",
        "categories": [
          {
            "code": "A00",
            "title": "Cholera",
            "includes": ["Vibrio cholerae infection"],
            "excludes": ["Carrier state"],
            "subcategories": [
              {
                "code": "A00.0",
```

```
{
  "code": "A00.1",
  "title": "Cholera due to Vibrio cholerae 01, biovar eltor"
},
{
  "code": "A00.1",
  "title": "Cholera due to Vibrio cholerae 01, biovar cholerae"
}
]
```

Example

```
